

Figure 5. Minute-level fragmentation phenotype: olfactory dysfunction associates with symmetric transition shifts, longer sedentary bouts, and uniform across-day pattern

A. Transition probabilities

B. Bout-length distributions

C. Heavy-tail prolonged-sitting exposure

D. Time-of-day decomposition

M4-adjusted estimates from minute-level PAXMIN_H data (n = 2,327). Diamonds: q < 0.05 after BH-FDR within panel; circles: not significant. Red: positive OD effect; blue: negative. Panel A: family of 3 (transitions/wake-hour omitted, q = 0.296). Panel B: family of 8. Panel C: family of 2. Panel D: family of 6. Together, the symmetric ASTP+/SATP- pattern in Panel A and the uniform across-day pattern in Panel D are consistent with a constitutive rather than time-locked or activity-specific behavioral shift; the underlying mechanism cannot be identified from these data.
